**Introduction**

The highly lipophilic nature of the carbocyanine dyes DiI, CM-DiI, DiO and DiD has often posed an obstacle to uniform cellular labeling in aqueous culture media. This technical difficulty has somewhat limited the use of these tracers in cell–cell fusion, cellular adhesion and migration applications for which their properties of low cytotoxicity and high resistance to intercellular transfer make them otherwise ideally suited. The structurally related PKH dyes have been developed and optimized for these applications. However, PKH dye labeling protocols require suspension of cells in an iso-osmotic mannitol loading medium. Molecular Probes’ Vybrant™ DiI cell-labeling solution is a dye delivery solution that can be added directly to normal culture media to uniformly label suspended or attached culture cells. The complementary Vybrant DiO and DiD cell-labeling solutions allow cell populations to be marked in distinctive fluorescent colors for identification after mixing (Figure 1). Cells that have fused or formed stable clusters can be identified by double labeling (Figure 2).

**Storage and Handling**

Vybrant DiI, CM-DiI, DiO and DiD cell-labeling solutions are supplied in units of 1 mL. The solutions contain 1 mM DiI, DiO or DiD, and have been filtered through 0.2 µm polycarbonate filters. The DiI, CM-DiI and DiD solutions contain ethanol; the DiO solution contains dimethylformamide (DMF). Unused portions that are not required for immediate use should be stored tightly sealed and protected from light at room temperature (V-22885, V-22886, V-22887) or at -20°C (V-22888).

**Experimental Protocols**

**Labeling of Cells in Suspension**

1.1 Suspend cells at a density of $1 \times 10^6$/mL in any chosen serum-free culture medium (note A).

1.2 Add 5 µL of the cell-labeling solution supplied per mL of cell suspension. Mix well by gentle pipetting.

1.3 Incubate for 1–20 minutes at 37°C. The optimal incubation time will vary depending on cell type. Typical incubation times required to produce uniform staining are shown in Table 1 (note B). For cell types other than those listed, start by incubating for 20 minutes and subsequently optimize as necessary to obtain uniform labeling.

1.4 Centrifuge the labeled suspension tubes at 1500 rpm for 5 minutes, preferably at 37°C.

1.5 Remove the supernatant and gently resuspend the cells in warm (37°C) medium.

1.6 Repeat the wash procedure (1.4 and 1.5) two more times.

![Figure 1. Normalized fluorescence emission spectra of DiO, DiI and DiD bound to phospholipid bilayer membranes.](image1)

![Figure 2. Polyethylene glycol-induced fusion of Jurkat cells detected by flow cytometry. Two populations of Jurkat cells were separately labeled, one with Vybrant DiI cell-labeling solution and the other with Vybrant DiO cell-labeling solution, following the protocols described in this product information sheet. Equal portions (1 mL) of the labeled cell suspensions were combined and treated with polyethylene glycol for 45 seconds to induce fusion. The mixed cell population was analyzed by flow cytometry (Becton-Dickinson FACSVantage). Double-labeled fused cells appear in the upper right quadrant of this bivariate correlation plot.](image2)
1.7 Allow 10 minutes recovery time before proceeding with fluorescence measurements.

**Notes**

[A] Cell suspension densities >1 × 10^7/mL or <1 × 10^5/mL require much longer incubation times for uniform staining to be obtained.

[B] Uniform staining was not obtainable in our tests on certain cell types (e.g. mouse monocyte macrophages and MDCK cells).

**Labeling of Adherent Cells**

2.1 Culture adherent cells on sterile glass coverslips as either confluent or subconfluent monolayers.

2.2 Remove coverslips from growth medium and gently drain off excess medium by touching the edge of the coverslip with blotting paper. Place coverslip in a humidity chamber.

2.3 Prepare staining medium by adding 5 µL of the supplied dye labeling solution to 1 mL of normal growth medium.

2.4 Pipet 100 µL of the staining medium onto the corner of a coverslip and gently agitate until all cells are covered.

2.5 Incubate the coverslip at 37°C. The optimal incubation time will vary depending on the cell type. Incubation times for selected cell types that have been tested in our laboratories are shown in Table 1 (note B). For cell types other than those listed, start by incubating for 20 minutes and subsequently optimize as necessary to obtain uniform labeling.

2.6 Drain off the staining medium and wash the coverslips three times. For each wash cycle, cover the cells with fresh, warmed growth medium, incubate for 10 minutes and then drain off the medium.

**Detection Configurations**

**Microscopy**

Filter sets for detection of DiI, DiO and DiD are selected based on their spectral characteristics, as summarized in Table 2. Multiband filter sets are available for simultaneous detection of multiple tracers as follows:

- DiI and DiO = Omega XF52, Chroma 51004
- DiI and DiD = Omega XF92, Chroma 51007
- DiI, DiO and DiD = Omega XF93, Chroma 61005

Omega® filters are supplied by Omega Optical, Inc. (www.omegafilters.com). Chroma filters are supplied by Chroma Technology Corp. (www.chroma.com).

**Flow Cytometry**

Cells labeled with DiI, DiO and DiD can be analyzed using the conventional FL2, FL1 and FL3 flow cytometer detection channels, respectively.

### Table 1. Optimal incubation times for cell staining with Vybrant DiI cell-labeling solution.
